

Game Scenario & Role

- Scenario: I'm building a text-based trivia game called "Data Analytics Jeopardy" where the player selects programming and data categories, answers trivia questions and tracks their score.
- Role: The program acts as the game moderator that displays categories, evaluates the player's answers, updates their score, and loops through rounds until the player decides to wrap up.

Program Components & Constraints

- Choices & Events: Different modules for category selection, presenting trivia questions, and evaluating user input.
- Variables & Stats:

score (Integer tracking points earned)

questionsAnswered (Integer counting how many questions get completed)

shouldRepeat (String flag set to "Yes" to keep playing or "No" to exit)

- Constraints: Each turn requires a valid choice input and the loop continues as long as the player wants to keep playing.

Logical Steps (Pseudocode Outline)

1. Start Up:

Set score = 0

Set questionsAnswered = 0

Set shouldRepeat = "Yes"

2. Main Game Loop (while shouldRepeat == "Yes"):

Call displayCategories() to show trivia options.

Get the user's selection and answer.

Evaluate the answer and update stats (score and questionsAnswered).

Ask: "Play another round? (Yes/No)" and save the answer to shouldRepeat.

3. End Game:

Print out a summary of the final stats (total score and questions answered) and a closing message.
